INTRODUCTION

The purpose of this Hydrology Study/Report is to provide adequate information regarding the water usage for a proposed cannabis cultivation operation and its impacts to surrounding areas. This report was written to meet the requirements of an Urgency Ordinance requiring land use applicants to provide enhanced water analysis during a declared drought emergency, approved by the Lake County Board of Supervisors on July 27th, 2021 (Attachment A – Urgency Ordinance No. 3106).

PROJECT DESCRIPTION

17870 Little High Valley, LLC (LHV) is seeking a Major Use Permit from the County of Lake for a proposed outdoor commercial cannabis cultivation operation at 17870 Little High Valley Road near Lower Lake, CA on Lake County APN 012-061-03 (Project Parcel). The proposed cultivation operation would be composed of 87,120 ft² of outdoor cultivation/canopy area and a 3,500 ft² Processing Facility (**Attachment B – Existing and Proposed Conditions Site Plans**). All water for the proposed cultivation operation would come from an existing onsite groundwater well located at Latitude: 38.86856° and Longitude: -122.57838°.

The 78.4-acre Rural Lands-zoned Project Parcel is located within the Copsey Creek watershed (HUC12) on a broad north-south trending ridge between Excelsior and Little High Valleys (Figure 1: Site Location Map). The Project Parcel is accessed via a shared private gravel and native soil surfaced access road off of Little High Valley Road. An unnamed ephemeral Class III watercourse forms in the southwest corner of the Project Parcel, and flows from northeast to southwest into an unnamed tributary of Copsey Creek.

Soils of the Project Parcel are identified primarily as the Collayomi-Whispering complex, the Konocti-Hambright complex, and the Stonyford-Guenoc complex by the NRCS Web Soil Survey, and characterized as well drained gravelly clay loams derived from residuum weathered from basalt, metavolcanics, and andesite. The United States Geological Survey Map of the Santa Rosa Quadrangle defines the area in the vicinity of the Project Property as Clear Lake Volcanics, composed of dacite, andesite, basalt, rhyolite, tuff and other pyroclastic rocks. The Project Parcel and existing onsite groundwater well are located within the Clear Lake Pliestocene Volcanic Ar. Groundwater Management Plan Area/Clear Lake Volcanics Groundwater Source Area as identified in the 2006 Lake County Groundwater Management Plan¹. Groundwater in the Clear Lake Volcanics occurs primarily in fractures, joints, and within weathered zones that formed in between volcanic eruptions.

The proposed outdoor cultivation/canopy areas would be enclosed with 6-foot tall chain link fences, with locking metal gates and privacy mesh/screen. The growing medium of the proposed outdoor cultivation/canopy areas would be an imported organic soilless growing medium (composed mostly of composted forest material) in aboveground garden beds. Drip irrigation systems would be used to deliver irrigation water to the aboveground fabric pots. Water from the onsite groundwater well would be pumped to eight proposed 2,500-gallon water storage tanks located upslope and north of the proposed outdoor cultivation/canopy areas. Irrigation water would be gravity fed from the water storage tanks to the drip irrigation systems of the proposed cultivation/canopy areas, via HDPE water supply lines.

Figure 1 – Site Location Map

WATER USAGE

Cannabis has often been characterized as a high-water-use plant. Bauer et al. (2015)² and Carah et al (2015)³ estimate that cannabis plants can consume up to approximately 6 gallons per plant per day, whereas grapes consume approximately 3.5 gallons per plant per day in the North Coast region of California. Other authors, however, have reported that water use requirement for cannabis plants are similar to those of other agricultural crops, such as corn and hops, with an estimated water use requirement of 25-35 inches per year (Hammon et al. 2015⁴). According to a recent study published in the Journal of Environmental Management (Dillis et al. 2020⁵), outdoor and mixed-light cannabis cultivation uses the most water during the months of August, with an estimated water use of approximately 58,704 gallons per acre during the month of August.

According to LHV's Property Management Plan, they expect a total annual water use requirement of 4.6 acre-feet or approximately 1,493,480 gallons for irrigation purposes, with the greatest daily water usage during the months of July, August, and September (approximately 8,265 gallons per day). LHV's maximum total proposed cannabis cultivation/canopy area is 87,120 ft². Using the water use requirements outlined in Hammon et al. 2015⁴, we estimate that the proposed cultivation operation would have an annual water use requirement between 4.2 and 5.8 acre-feet. The

following table presents the expected water use of the proposed cultivation operation in gallons by month during the cultivation season (April through November), using water usage information provided in LHV's Property Management Plan.

	April	May	June	July	August	September	October	November
Low (25"per year)	75,000	150,000	190,000	230,000	260,000	230,000	150,000	75,000
High (35" per year)	100,000	200,000	280,000	325,000	370,000	325,000	200,000	100,000

Based on the water use estimates above, we estimate that the proposed cultivation operation would have a maximum daily water use requirement of approximately 12,333 gallons, with an average daily water use requirement between 5,040 and 7,040 gallons per day during the cultivation season (April through November).

WATER AVAILABILITY

The Project Parcel is located within the Clear Lake Volcanics Groundwater Source Area as identified in the 2006 Lake County Groundwater Management Plan¹. The Clear Lake Volcanics consist of basalt, andesite, and other volcanic rocks in a complex sequence. Groundwater in the Clear Lake Volcanics occurs primarily in fractures, joints, and within weathered zones that formed in between volcanic eruptions. The amount of groundwater available to a well in the formation is highly dependent on the size, openness, frequency, and interconnection of fractures and joints encountered in the well.

All water for the proposed cultivation operation would come from the existing onsite groundwater well located at Latitude: 38.86856° and Longitude: -122.57838°, near the center of the Project Parcel and directly adjacent to the proposed cultivation operation. This groundwater well was drilled to a depth of 320 feet below ground surface (bgs) in August of 2020, through red clay with basalt boulders (0-50 feet bgs), volcanic ash (50-75 feet bgs), and red and black volcanics (75-320 feet bgs). This well had an estimated yield of +400 gallons per minute (gpm) at the time it was drilled (Attachment C: Onsite Well Completion and Performance Test Reports). Based on the information provided in the Well Completion Report, it appears that the onsite well receives groundwater from a confined aquifer located beneath the Project Parcel.

On January 15th, 2021 Cal-Tech Pump Well & Water Treatment (License No. 923640) conducted a 4-hour well performance test of the onsite groundwater well. During the well performance test, the water level in the onsite groundwater well was monitored while it was pumped at 55.5 gpm. The static water level in the onsite groundwater well was 180 feet bgs prior to the start of the well performance test. During the well performance test, the water level in the onsite groundwater well dropped to 195 feet bgs (**Attachment C: Onsite Well Completion and Performance Test Reports**). The water level within the well recovered to 186 feet bgs within 30 minutes after the pumping ceased. A Specific Capacity of 3.7 gpm/foot of drawdown (i.e., 55.5 gpm / 15 feet) was calculated from the well performance test data.

The well yield test data indicates that the onsite groundwater well can produce approximately 3.7 gpm for every foot of drawdown, and at least 55.5 gpm. The well recovery observations

demonstrate that the well may be able to produce this water without causing overdraft conditions. The peak anticipated daily demand for water of the proposed cultivation operation is \sim 12,333 gallons per day, which the onsite groundwater well could produce in less than 3 hours and 45 minutes, when pumped at 55.5 gpm. Additionally, LHV proposes to establish at least 20,000 gallons of water storage capacity on the property. Based on the well performance test data and the estimated water use requirements of the proposed cultivation operation, it appears that the existing onsite groundwater well could sustainably produce the water needed to meet the project demands.

AQUIFER/GROUNDWATER RECHARGE

Groundwater recharge is the replenishment of an aquifer with water from the land surface. It is usually expressed as an average rate of inches of water per year, similar to precipitation. Thus, the volume of recharge is the rate multiplied by the land area under consideration times the time period, and is usually expressed as acre-ft per year. In addition to precipitation, other sources of recharge to an aquifer are stream and lake or pond seepage, irrigation return flow (both from canals and fields), inter-aquifer flows, and urban recharge (from water mains, septic tanks, sewers, and drainage ditches).

To estimate the groundwater recharge at the site, we first must assume that the recharge to the aquifer is primarily through rainfall across the 78.4-acre Project Parcel (Lake County APNs 003-046-02). Therefore, the annual precipitation available for recharge onsite can initially be estimated using the following data and equation.

78.4 acres x 2.75 feet (Average Annual Precipitation for Clearlake, CA) = 216 acre-feet Estimated Annual Precipitation Onsite = 216 acre-feet/year

However, this estimate does not account for surface run-off, stream underflow, and evapotranspiration that occurs in all watersheds. According to the USGS, the long-term average precipitation that recharges groundwater in the northern California region is approximately 15 percent. Since the soils of and geology of/under the Project Parcel are typical for the northern California region, we can estimate that the long-term average precipitation that recharges groundwater within the entire site to be at least 10 percent. With this data and the precipitation data presented above, we can estimate the groundwater recharge of the Project Parcel by using the following equation.

216 acre-feet/year (annual precipitation onsite) x 0.10 (long term average recharge) = Estimated Groundwater Recharge = 21.6 acre-feet/year

Based on the estimated average annual recharge to the aquifer under the Project Parcel (~22 acrefeet/year) and the estimated annual water usage of the proposed cultivation operation (4.2 and 5.8 acre-feet/year), it appears that LHV will have enough water to meet their demands without causing overdraft conditions.

However, the estimates above do not account for severe drought conditions, as we have seen over the last decade. The California Department of Water Resources ranked Water Year 2021 (October 1st, 2020 through September 30th, 2021) as the State's fourth driest on record. During Water Year 2021, less than 10 inches (approximately 9.5 inches) of precipitation fell on the USGS Cache Creek Precipitation Gage near Lower Lake, CA (closest USGS Precipitation Gage to the Project

Property). If we rerun the calculations above using this precipitation data, we can obtain the following estimate for groundwater recharge during Water Year 2021.

78.4 acres x 0.8 feet (Water Year 2021 Precipitation for Lower Lake, CA) = 62.7 acre-feet 62.7 acre-feet (Water Year 2021 Onsite Precip) x 0.10 (long term average recharge) = Estimated Severe Drought Value for Groundwater Recharge = 6.3 acre-feet

The estimated amount of water available to recharge the aquifer under the Project Property during a severe drought year (\sim 6.3 acre-feet) is still greater than the estimated annual water usage of the proposed cultivation operation (4.2 to 5.8 acre-feet).

POTENTIAL IMPACTS TO STREAMS & NEIGHBORING WELLS

Urgency Ordinance 3106 requires analysis of the "Cumulative impact of water use to surrounding areas due to project" implementation. To do this, we must first identify surrounding areas and uses that could be impacted from the project's well pumping/water usage. As outlined in previous sections of this report, all water for the proposed cultivation operation would come from an existing onsite groundwater and the proposed cultivation operation would have an annual water use requirement between 4.2 and 5.8 acre-feet (1,369,000 to 1,890,000 gallons) per year.

To evaluate potential well pumping impacts to surrounding areas and uses, the potential lateral extent of pumping from the onsite groundwater well was estimated. Using general relationships discussed in Groundwater and Wells, Second Edition (Driscoll 1986⁶), we estimate the lateral pumping influence using information from the onsite groundwater well's Well Completion Report and from the well performance test performed by Cal-Tech Pump Well & Water Treatment January 15th, 2021 (Attachment C: Onsite Well Completion and Performance Test Reports). An approximate relationship between specific capacity calculated from the well performance test and aquifer transmissivity was used to obtain aquifer characteristics and estimate a potential radius of pumping influence. Transmissivity was estimated for a confined aquifer, using the relationship of specific capacity (yield/drawdown) multiplied by the coefficient of 2,000 (for a confined aquifer). To develop the slope of the drawdown curve from the pumping well, the value of Δ s (drawdown over on log graph cycle) was calculated for a distance-drawdown relationship, where T = 528Q/ Δ s (Driscoll 1986, equation 9.11⁶). The analysis is shown on the attached semi-log plot (Attachment D – Radius of Influence Analysis).

Using data from the Well Completion and Performance Test Reports and the general relationships outlined above, we calculated a zone of pumping influence extending approximately 2,000 feet from the onsite groundwater well. There are several unnamed ephemeral Class III watercourses within 2,000 feet of the onsite groundwater well, but ephemeral watercourses do not support aquatic habitat and are typically dry by April of each year, when pumping for the proposed cultivation operation would begin. Therefore, the potential for stream depletion as a result of the proposed onsite groundwater usage is not considered a concern to this assessment.

The Project Parcel is located in the southeast corner of Section 24 of Township 12 North and Range 7 West. The Well Completion Reports for all wells filed with the California Department of Water Resources (DWR) within Section 24 and the three adjoining Sections (Township 12N, Range 6W, Sections 19 & 30 and Township 12N, Range 7W, Section 25) were reviewed for this Hydrology Report. DWR's Well Completion Report Map Application indicates that there are forty-two (42)

wells located within these four sections. Well log data from those Well Completion Reports are summarized in a table attached to this report (Attachment E – Nearby Wells Inventory). Additionally, the Lake County Environmental Health Department was consulted to determine the presence of any wells on the parcel adjacent to the Project Parcel.

The Lake County Environmental Health Department and DWR both had records indicating that there was one offsite groundwater well within a 2,000-foot radius from the onsite groundwater well, located at 12999 Spruce Grove Road on Lake County APN 012-067-35. As part of our research for this Hydrology Report, we contacted the landowner of APN 012-067-35 on January 26, 2022. The landowner indicated that the well was not currently in use and that he planned to use it as a domestic water source for a future residence. According to the Well Completion Report for the groundwater well located at 12999 Spruce Grove Road (Attachment F – Nearest Known Neighboring Well Completion Report), this well was drilled to a depth of 180 feet bgs in May of 2021, through red clay with volcanic boulders (0-20 feet bgs), black shale and sandstone (20-140 feet bgs), and black sandstone with gravels (140-180 feet bgs). The Well Completion Report does not indicate the exact location of the well located at 12999 Spruce Grove Road, but the landowner was kind enough to provide us with its location (Figure 2 – Area of Influence Diagram).

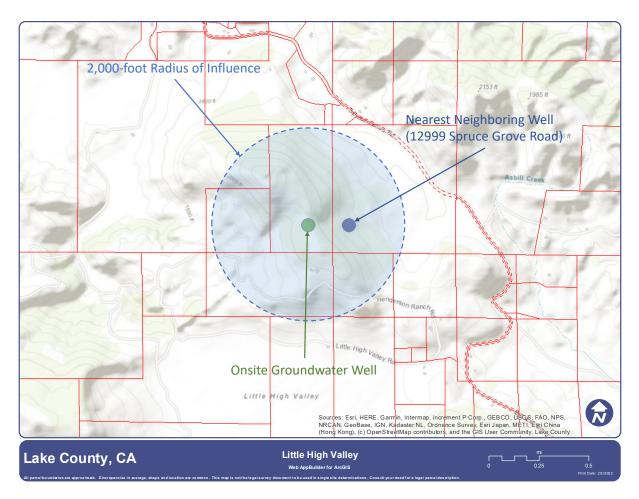

Figure 2 – Area of Influence Diagram

The wellhead of the onsite groundwater well is located at approximately 2,060 feet above mean sea level, and the well is screened between 220 and 320 feet bgs (~1,840 to ~1740 feet above mean sea level). The wellhead of the nearest known neighboring groundwater well is located at approximately 1,800 feet above mean sea level, and the well is screened between 140 and 180 feet bgs (~1,660 to ~1,620 feet above mean sea level). Both the onsite groundwater well and the nearest known neighboring groundwater well were drilled by Will Peterson Well Drilling. Will Peterson Well Drilling described the aquifer in which the onsite groundwater well was screened as "red/black volcanics", and described the aquifer in which the nearest neighboring groundwater well were well was screened as "black sandstone with gravels". Based on the information provided in the Well Completion Reports, it appears that the onsite well and nearest neighboring well receive groundwater from two different confined aquifers. Therefore, given the horizontal and vertical separations between the onsite groundwater well and neighboring wells, it does not appear that pumping for the proposed cultivation operation will result in well interference.

DROUGHT MANAGEMENT PLAN

The Urgency Ordinance approved by the Lake County Board of Supervisors on July 27th, 2021 (Ordinance No. 3106) requires applicants to provide a plan depicting how the applicants plan to reduce water use during a declared drought emergency. LHV proposed cultivation operation would be composed of 87,120 ft² of outdoor cultivation/canopy area and a 3,500 ft² Processing Facility. All water for the proposed cultivation operation would come from an existing onsite groundwater well located at Latitude: 38.86856° and Longitude: -122.57838°, and the proposed cultivation operation would have an annual water use requirement between 4.2 and 5.8 acre-feet per year/cultivation season. As outlined above, we do not anticipate any impacts to streams and/or neighboring wells as a result of pumping of the onsite groundwater well for the proposed cultivation.

Per the Water Conservation and Use requirements outlined in the State Water Resources Control Board's Cannabis General Order, LHV shall implement the following Best Practical Treatment and Control (BPTC) measures to conserve water resources:

- Regularly inspect the entire water delivery system for leaks and immediately repair any leaky faucets, pipes, connectors, or other leaks;
- Apply weed-free mulch in cultivation areas that do not have ground cover to conserve soil moisture and minimize evaporative loss;
- Implement water conserving irrigation methods (drip or trickle and micro-spray irrigation);
- Maintain daily records of all water used for irrigation of cannabis. Daily records will be calculated by using a measuring device (inline water meter) installed on the main irrigation supply line between the water storage area and cultivation area(s);
- Install float valves on all water storage tanks to keep them from overflowing onto the ground.

With the Water Conservation and Use requirements outlined above, the proposed cultivation operation would efficiently use water resources at all times. Additionally, Article 27 Section 27.11 of the Lake County Zoning Ordinance requires commercial cannabis cultivators using water from a groundwater well to install a water level monitor on their water supply well, and to regularly

record readings from the continuous water level monitor. Well water level monitoring and reporting shall be performed as follows:

Seasonal Static Water Level Monitoring

Seasonal monitoring of well water levels provides information regarding long-term groundwater elevation trends. The water level in the onsite groundwater well shall be measured and recorded prior to the start of the cultivation season (March/April), and once in the fall (November) after the cultivation season has ended. Data reported to the Lake County Community Development Department as part of the Project's annual reporting requirements shall include a hydrograph plot of all seasonal water level measurements for the onsite groundwater well.

Water Level Monitoring During Extraction

The purpose of monitoring the water level in a well during extraction is to evaluate the performance of the well to determine the effect of the pumping rate on the water source during each cultivation season. This information can be used to determine the capacity and yield of the onsite groundwater well for determining pump rates and the need for water storage. The frequency of water level monitoring will depend on the source, the source's capacity, and the pumping rate. It is recommended that initially the water level be monitored twice per week or more, and that the frequency be adjusted as needed depending on the impact the pumping rate has on the well water level. Data reported to the Lake County Community Development Department as part of the Project's annual reporting requirements shall include a hydrograph plot of the water level readings during the cultivation season.

In addition to the monitoring and reporting described above, the Project's annual report shall include an analysis of the water level monitoring data, demonstrating whether or not use of the onsite groundwater well is causing significant drawdown and/or impacts to the surrounding area and what measures were taken to reduce impacts. If there are impacts, a revised Water Management Plan shall be prepared and submitted to the Lake County Community Development Department, for review and approval, demonstrating how the project will mitigate the impacts in the future.

DROUGHT EMERGENCY RESPONSE

When a drought emergency has been declared for the area of the proposed cultivation operation, LHV may implement the following additional measures, as needed or appropriate to the site, to reduce water use and ensure both success of the cultivation operation and decreased impacts to surrounding areas:

- Install moisture meters to monitor how much water is in the soil at the root level and reduce watering to only what is needed to avoid excess;
- Irrigate only in the early morning hours or before sunset;
- Cover plants with shaded meshes during peak summer heat to reduce plant stress and water needs;
- Add a soil amendments/ingredients to growing medium that retains water in a way to conserve water and aid plant growth/health. Soil amendments/ingredients such as peat moss, coco coir, compost, perlite, and vermiculite retain water and provide a good environment for cannabis to grow.

Additionally, to ensure both success and decreased impacts to the surrounding areas, LHV plans to reduce their outdoor cultivation/canopy area and water usage by 10 percent, when a drought emergency has been declared for their region. To reduce their water usage by 10 percent, LHV

will not plant 8,712 ft² or more of their proposed cultivation/canopy area. The cultivation/canopy area(s) to be left fallow will depend on when a drought emergency is declared (before or after the proposed cultivation/canopy areas have been planted), and LHV will prioritize the preferred cultivation/canopy areas over less desirable cultivation/canopy areas (based on cultivation experience). By implementing the Drought Management Plan outlined above, LHV would reduce their estimated annual water demand from 1,369,000 to 1,890,000 gallons, to 1,232,100 to 1,701,000 gallons (10 percent), during periods of drought.

CONCLUSIONS

All water for the proposed cultivation operation will come from the existing onsite groundwater well located at Latitude: 38.86856° and Longitude: -122.57838°. This groundwater well was drilled to a depth of 320 feet below ground surface in August of 2020, with an estimated yield of +400 gallons per minute (gpm) at the time it was drilled. A well performance test performed in January of 2021, indicates that the onsite groundwater well can sustainably produce at least 55.5 gallons per minute. From the well performance test data we calculated a Specific Capacity of approximately 3.7 gpm/foot for the onsite groundwater well. The total estimated annual water use requirement for the proposed cultivation operation is between 1,369,000 to 1,890,000 gallons per year.

Based on data from the recent well performance test and the estimated water use requirement(s) for the proposed cultivation operation, it appears that the onsite groundwater well is a sufficient water source for the proposed cultivation operation. Based on the estimated average annual recharge to the aquifer under the Project Property (~21.6 acre-feet/year) and the estimated annual water usage of the proposed cultivation operation (4.2 to 5.8 acre-feet/year), it appears that the aquifer storage and recharge area are sufficient to provide for sustainable annual water use at the site and on the Project Property.

The calculated zone of pumping influence for the proposed cultivation operation extends approximately 2,000 feet from the onsite groundwater well. There is a neighboring well within 2,000 feet of the onsite well, but this well appears to receive water from a confined aquifer that is different from the aquifer from which the onsite well receives groundwater (based on the Well Completion Reports for the two wells). Therefore, it does not appear that pumping for the proposed cultivation operation will impact neighboring wells, given the horizontal and vertical separations between the onsite groundwater well and the nearest known wells. Pumping for the proposed cultivation operation should not impact nearby ephemeral watercourses, as they are typically dry by April of each year, when pumping for the proposed cultivation operation would start.

LHV's Drought Management Plan is to reduce their outdoor cultivation/canopy area and water usage by 10 percent, to ensure both success and decreased impacts to the surrounding areas during a drought emergency. The cultivation/canopy area(s) to be left fallow will depend on when a drought emergency is declared, prioritizing the preferred cultivation/canopy areas over less desirable cultivation/canopy areas. By implementing their Drought Management Plan, Little High Valley would reduce their estimated annual water demand from 1,369,000 to 1,890,000 gallons, to 1,232,100 to 1,701,000 gallons, during periods of drought.

LIMITATIONS

Realm Engineering is not responsible for the independent conclusions, opinions or recommendations made by others based on the records review, site inspection, field exploration, and interpretations presented in this report.

Groundwater systems of Lake County are typically complex, and available data rarely allows for more than general assessment of groundwater conditions and delineation of aquifers. Hydrologic interpretations are based on Well Completion Reports made available to us through the California Department of Water Resources, available geologic maps and hydrological studies and professional judgment. This analysis is based on limited available data and relies significantly on interpretation of data from disparate sources of disparate quality.

It should be noted that hydrological assessments are inherently limited in the sense that conclusions are drawn and recommendations developed from information obtained from limited research and site evaluation. Additionally, the passage of time may result in a change in the environmental characteristics at this site and surrounding properties. This report does not warrant against future operations or conditions, nor does this warrant operations or conditions present or a type or at a location not investigated.

This report is for the exclusive use of 17870 Little High Valley, LLC, their affiliates, designates and assignees, and no other party shall have any right to rely on any service provided by Realm Engineering without prior written consent.

Please feel free to contact me with any questions that you may have regarding this Hydrology Study/Report.

Sincerely, Jason Vine, P.E. 67800

ATTACHEMENT A

URGENCY ORDINANCE NO. 3106

BOARD OF SUPERVISORS, COUNTY OF LAKE, STATE OF CALIFORNIA

ORDINANCE NO. 3106

AN URGENCY ORDINANCE REQUIRING LAND USE APPLICANTS TO PROVIDE ENHANCED WATER ANALYSIS DURING A DECLARED DROUGHT EMERGENCY

WHEREAS, the Sheriff, acting as the OES Director of Lake County, declared a local emergency due to drought conditions on May 6, 2021; and

WHEREAS, the Lake County Board of Supervisors approved the ratification of the declaration of a local emergency due to drought conditions on May 11, 2021; and

WHEREAS, the Board of Supervisors wish to ensure continued access to drinking water from private wells or from water purveyors throughout the county; and

WHEREAS, the Board of Supervisors wish to ensure that all current agricultural activities and projects find success during this declared drought emergency; and

WHEREAS, the Board of Supervisors of the County of Lake finds that additional information is critical to ensuring that the Planning Commission approves projects based on evidence of water use and water impacts and the analysis of the impacts to the surrounding areas.

NOW THEREFORE, the Board of Supervisors of the County of Lake hereby ordains as follows:

<u>Section One:</u> Due to the exceptional drought that we are experiencing and the declaration of a drought emergency, any land use approvals are required to provide adequate information regarding water usage for the project being considered and its impacts to surrounding areas. All projects that require a CEQA analysis of water use must include these additional items:

- A. Hydrology report prepared by a California licensed civil engineer, hydro-geologist, hydrologist, or geologist experienced in water resources
 - a. Approximate amount of water available for the project's identified water source
 - b. Approximate recharge rate for the project's identified water source
 - c. Cumulative impact of water use to surrounding areas due to project
- B. Drought Management Plan
 - Provide a plan depicting how the applicants plan to reduce water use during a declared drought emergency, to ensure both success and decreased impacts to the surrounding areas

<u>Section Two</u>: This urgency ordinance, if approved, shall take effect on all future Planning Commission considerations until the declared drought emergency has expired or if the Board of Supervisors revokes the ordinance.

Section Three: It can be seen with certainty that there is no possibility that this urgency Ordinance may have a significant effect on the environment.

Section Four: All ordinances or parts of ordinances or resolutions or parts of resolutions in conflict herewith are hereby repealed to the extent of such conflict and no further.

Section Five: This ordinance shall go into effect immediately, and before the expiration of fifteen days after its passage, it shall be published at least once in a newspaper of general circulation printed and published in the County of Lake.

Section Six: This Ordinance is adopted as an urgency Ordinance pursuant to the provisions of Government Code sections 25123 and 25131 and shall be effective immediately upon adoption. Based on the declaration of purpose and facts constituting the urgency set forth above in Section One of this Ordinance, the Board of Supervisors finds and determines that the adoption of this Ordinance as an urgency Ordinance is necessary for the immediate preservation of the public peace, health and safety to address critical groundwater conditions in Lake County.

AYES: Supervisors Simon, Crandell, Scott, Pyska, and Sabatier

NOES: None

ABSENT OR NOT VOTING: None

NOTES & RECOMMENDATIONS:

Well casing is above grade, and it has a proper seal. Pump is set 273' on 2" galvanized drop pipe.

ATTACHEMENT D

RADIUS OF INFLUENCE ANALYSIS

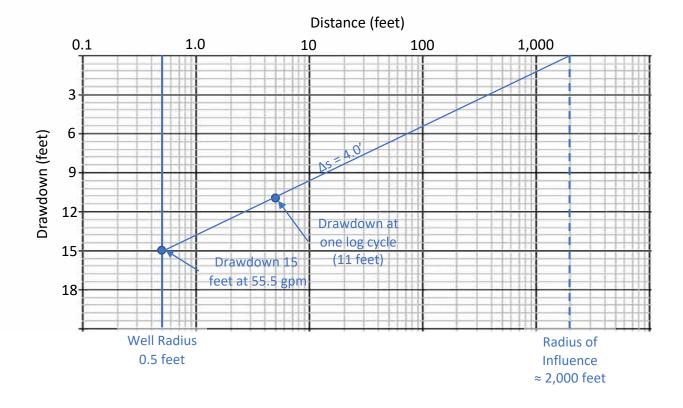

Radius of Influence Analysis

Well Radius (from Well Water Yield & Inspection Report) = 12"/2 x 1'/12" = 0.5 feet

Specific Capacity (using data from 1/15/21 Well Performance Test) 55.5 gpm (yield) / 15 feet (drawdown) = 3.7 gpm/foot of drawdown Specific Capacity (SC) = 3.7

Modified Jacob's equation from Driscoll Appendix 16-D (Driscoll 1986⁶) Transmissivity Confined Aquifer T = SC x 2000; T = 7,400 gpft/day

Distance Drawdown Equation Driscoll 9.11 (Driscoll 1986⁶) T=528Q/ Δ s Δ s = 528Q/T; Δ s = 528 x 55.5 gpm / 7,400 Δ s = 4.0'
